Feto-Infant Mortality in Public Health Region 6/5 South, 2010-2014

About Perinatal Periods of Risk (PPOR)

- Based on birth weight and age at death, fetal and infant deaths are partitioned into four corresponding risk periods
- These four periods have different risk factors and causes of death, and hence, different opportunities for prevention
- These four risk periods represent distinct points of intervention in the health care continuum (Figure 1)
- Region 6/5 South and specific study populations are compared to a state-level reference group generally known to have better feto-infant mortality outcomes (i.e., non-Hispanic White women who are 20+ years of age and have 13+ years of education)

Phase I: Perinatal Period Comparison

Excess Feto-Infant Mortality in Texas

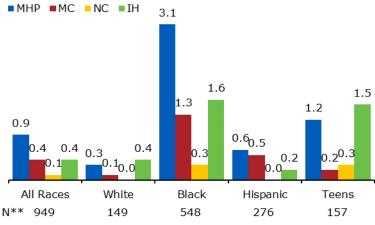

Feto-infant mortality rates* (F-IMR) were:

- 6.1/1,000 for White mothers
- 11.5 for Black mothers
- 6.5 for Hispanic mothers
- 8.5 for teen mothers

Excess F-IMR is the gap in F-IMR between the study population (i.e., Black, White, Hispanic or teens) and the reference group. Total excess F-IMR estimates were (Figure 2):

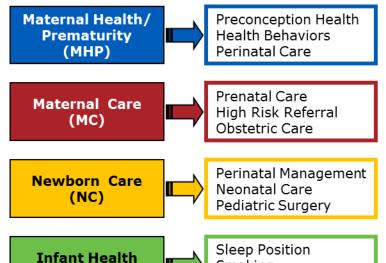

- 0.9 for White mothers
- 6.3 for Black mothers
- 1.3 for Hispanic mothers
- 3.3 for teen mothers

Figure 2: Excess Feto-Infant Mortality Rates

*F-IMR = # of fetal & infant deaths ≥500g and ≥24 weeks/
of live births & fetal deaths ≥500g and ≥24 weeks
**N = # of excess fetal and infant deaths

Figure 1: PPOR Risk Periods Points of Intervention

Sleep Position Smoking Injury Prevention

- Black mothers had the highest excess F-IMR in 3 of the 4 risk periods
- Potentially 55% of Black fetal and infant deaths were preventable (i.e., excess fetal and infant deaths)
- For Black mothers, 50% of all excess fetoinfant deaths occurred in the MHP risk period
- For teen mothers, 83% of excess fetoinfant deaths occurred in the MHP and IH risk periods

Recommendations

(IH)

- 1. Target interventions to Black populations for MHP, MC and IH-related deaths
- 2. Target interventions to teen mothers for MHP and IH-related deaths
- 3. Target MHP-related deaths among Hispanic populations
- 4. Target IH-related deaths among White populations

Area with the Greatest Potential Impact

Black Maternal Health/Prematurity Risk Period

Texas Department of State Health Services

Data Source: All data originate from Texas Department of State Health Services, Center for Health Statistics, 2010-2014

Phase II: Maternal Health and Prematurity (MHP) Period of Risk

The MHP risk period includes very low birth weight (VLBW) fetal and infant deaths (<1,500g)

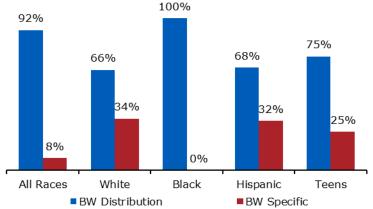

Birth Weight (BW) Distribution vs. Birth Weight (BW) Specific Mortality (Figure 3)

- The majority of MHP-related excess deaths were due to a greater number of VLBW births among the study populations compared to the reference group (a difference in BW distribution)
- Black infants had lower mortality rates among VLBW births than the reference population; for this study population, all excess deaths were potentially attributable to a greater number of VLBW births

BW Distribution Modifiable Risk Factors

- Weight gain less than 15 lbs. accounted for 19% of VLBW births
- Inadequate prenatal care contributed to 4% of VLBW births
- All study populations were more likely to gain less than 15 lbs. compared to the reference group
- All study populations were more likely to have inadequate prenatal care compared to the reference group

Figure 3: Excess MHP-Related Death Attributable to BW Distribution vs. BW Specific Mortality

BW Specific Modifiable Risk Factors

- 4% of VLBW infant deaths were attributable to inadequate prenatal care
- Congenital anomalies accounted for 2% of VLBW infants deaths
- All study populations had higher rates of inadequate prenatal care than the reference group

Recommendations

- Reduce the number of women gaining less than 15 lbs. during pregnancy
- Increase access to and utilization of prenatal care
- Reduce congenital anomalies

Phase II: Infant Health (IH) Period of Risk

The IH risk period includes infants weighing \geq 1,500g at birth and surviving \geq 28 days

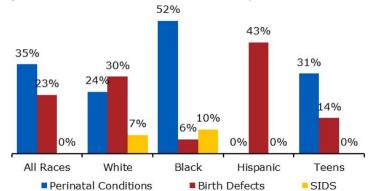

Causes of IH-Related Death (Figure 4)

- Perinatal conditions accounted for 35% of overall excess deaths in the IH risk period
- In Phase I, Black infants and infants born to teen mothers had the greatest excess mortality in the IH risk period
- Birth defects contributed to 30% of excess deaths among White infants and 14% among infants born to teen mothers
- SIDS accounted for 10% of excess deaths among Black infants and 7% among White infants

IH-Related Modifiable Risk Factors

- 4% of infant deaths were attributable to not receiving first trimester prenatal care
- Infants who were breastfed had 11% reduced risk of infant death

Figure 4: Excess IH-Related Death by Cause

Recommendations

- Reduce prematurity among all populations
- Reduce birth defects among White infants and infants born to teen mothers
- Reduce SIDS among Black infants and White infants
- Increase access to prenatal care
- Increase rates of breastfeeding

NOTE: Due to relatively small excess mortality, the newborn care and maternal care risk periods are not discussed Texas Department of State Health Services, Maternal & Child Health Epidemiology Unit (March 2018)
